The purpose of this study was to examine the impact of poverty on Pennsylvania Value-Added Assessment Scores (PVAAS) in mathematics, reading, and science. Due to the perceived under-performance of public schools in the United States of America, many reform efforts have been enacted. One such effort was the No Child Left Behind Act (NCLB) of 2002, which held school districts and individual schools accountable for student performance as measured by arbitrary achievement goals on state mandated assessments. Many critics of NCLB believed the accountability measure to be unfair as students enter school with varying educational experiences and intellectual ability levels. In response to this criticism, many states, including Pennsylvania, shifted to an accountability model that measures student growth from year to year. This model purports to eliminate variables beyond the control of schools and teachers, such as student poverty, intellectual ability, and prior educational experience. In Pennsylvania, the system used to measure student growth is known as PVAAS.

This study examined the PVAAS scores of 1,688 public schools in mathematics and reading and 1,659 schools in science to determine if the scores were influenced by poverty, as determined by student participation in the Free and Reduced Lunch program. Correlation coefficients were conducted utilizing
schools PVAAS scores in mathematics, reading, and science and the percentage of students identified as economically disadvantaged within the schools. Additionally, analysis of variance (ANOVA) were conducted in each subject after grouping schools based on the percentage of students who were economically disadvantaged.

The findings and conclusions of this study show that PVAAS scores may be influenced by poverty. Correlation coefficients suggest a small, negative relationship between poverty and PVAAS scores in math and a large, negative relationship in science. Additionally, ANOVA results indicate that statistically significant differences exist between groups based on concentration of poverty in all subjects studied. In total, the results suggest that as poverty within a school increases, PVAAS scores decline. Recommendations are based on how the relationship between the two might be further explored and how it can be shared with those skeptical of the value-added measure.
